CIS 430: DATA MINING & KNOWLEDGE DISCOVERY - Final Project Report

Project Title: Document Plagiarism Detector using Locality-Sensitive Hashing (LSH)

Student Name: Bhumika Battineni

Student ID: 02173043

Date: December 11, 2025

1. Background and Introduction

In the era of "Big Data," the volume of digital text generated daily—ranging from academic papers to news articles and social media posts—has grown exponentially. A critical challenge in managing this data is the detection of near-duplicate documents, a process essential for plagiarism detection, copyright enforcement, and news aggregation.

The fundamental difficulty in detecting plagiarism within large collections is scalability. A naive approach requires comparing every document against every other document to calculate similarity. For a collection of **N** documents, this results in **N(N-1)/2** comparisons, leading to a computational complexity of **$O(N^2)$**. As demonstrated in the preliminary analysis for this project, checking 10,000 documents would require approximately 50 million comparisons, taking over 14 hours to compute.

This research project addresses this scalability bottleneck by implementing a **Locality-Sensitive Hashing (LSH)** pipeline. LSH allows us to identify "candidate pairs"—documents that are likely to be similar—without exhaustively comparing every pair. This reduces the search space from quadratic **$O(N^2)$** to approximately linear **O(N)** time, making plagiarism detection feasible for real-world applications.

2. Related Work

The problem of near-duplicate detection is well-studied in computer science. Traditional methods rely on exact matching or edit distance (Levenshtein distance), which provide high accuracy but fail to scale for large datasets.

In industry, search engines like Google use algorithms such as SimHash and MinHash to detect duplicate web pages during crawling to avoid indexing redundant content. Similarly, plagiarism detection services like Turnitin utilize document fingerprinting techniques that share theoretical foundations with the methods explored in this project. Social media platforms like Twitter and Reddit also employ these hashing strategies to detect spam bots and reposts. This project distinguishes itself by implementing a complete MinHash and LSH pipeline from scratch in Python and applying it to the "20 Newsgroups" dataset to empirically verify the trade-offs between computational speedup and detection accuracy.

3. Problem Definition

We formally define the research problem as follows:

Given a large corpus of documents **D = {d1, d2, ..., dn}**, we aim to identify all pairs of documents **(di, dj)** such that their Jaccard similarity **J(di, dj)** exceeds a user-defined threshold **t**.

The **Jaccard Similarity** is defined as the size of the intersection of the feature sets of two documents divided by the size of their union:

$J(A, B) = |A \cap B| / |A \cup B|$

The specific constraints of this problem are:

1. **Threshold (t):** We define plagiarism as a similarity score **≥ 0.8** (80%).
2. **Efficiency:** The system must avoid calculating the exact Jaccard similarity for all pairs. It must utilize a probabilistic filter (LSH) to prune dissimilar pairs early in the pipeline.

4. Methodology

To solve this problem, I implemented a three-stage pipeline: **Shingling**, **MinHashing**, and **LSH Banding**. This methodology transforms heavy text processing into efficient integer comparison.

4.1. Stage 1: Shingling (Representing Documents as Sets)

The first step involves converting raw text strings into sets of **k**-shingles. A shingle is a contiguous subsequence of **k** characters. For this implementation, I selected **k = 5**.

- **Example:** The text "a rose is a rose" is converted into the set {'a ros', ' rose', 'rose ', 'ose i', ...}.
- **Hashing:** To optimize memory usage, each string shingle is hashed into a 32-bit integer. This converts every document into a set of integers.

4.2. Stage 2: MinHashing (Dimensionality Reduction)

Comparing the raw shingle sets is still computationally expensive because the sets are large (thousands of integers per document). MinHashing compresses these sets into short "signatures" while preserving the Jaccard similarity.

- **Technique:** We use **n = 100** random hash functions. For each document, we compute the minimum hash value produced by each function across all shingles in the document.
- **Property:** The probability that the MinHash values for two documents are equal is exactly their Jaccard similarity: **P(h_min(A) = h_min(B)) = J(A, B)**
- **Result:** A signature matrix of size **100 × N**, where each column represents a document's compact signature.

4.3. Stage 3: Locality-Sensitive Hashing (Finding Candidates)

Even with compact signatures, comparing 100 integers for every pair of documents is slow. LSH solves this by using a "banding" technique.

- **Banding:** The 100-number signature is divided into **b = 20** bands, each containing **r = 5** rows (**20 × 5 = 100**).
- **Bucketing:** For each band, the vector of 5 integers is hashed to a large bucket.
- **Candidate Selection:** If two documents hash to the same bucket in **at least one** band, they are flagged as a "candidate pair".
- **Intuition:** Similar documents are highly likely to collide in at least one band, while dissimilar documents are unlikely to collide.

4.4. Verification

Finally, for the small subset of candidate pairs identified by LSH, we compute the exact Jaccard similarity using the original shingle sets to verify if they meet the 80% threshold.

5. Experimental Setting

The experiments were conducted using the following environment and parameters:

- **Hardware/Software:** The system was implemented in Python using numpy for matrix operations and scikit-learn for data loading. It was executed on a MacBook Pro (Apple Silicon).
- **Dataset:** The **20 Newsgroups** dataset, a standard benchmark for text classification. To ensure a manageable scope for demonstration while retaining real-world complexity, I utilized three distinct categories: comp.graphics, sci.med, and talk.politics.mideast.
    - **Total Documents:** 2,903 documents.
- **Parameters:**
    - Shingle size (**k**): 5
    - Signature length (**n**): 100
    - LSH Bands (**b**): 20
    - Rows per band (**r**): 5
    - Plagiarism Threshold: 0.8 (80%).

6. Experimental Results and Analysis

The implementation was successful in identifying plagiarism with a massive reduction in computational cost.

6.1. Runtime Performance

The total pipeline executed in under 4 seconds for nearly 3,000 documents, a task that would have taken significantly longer using brute force.

- **Loading Data:** 0.65 seconds
- **Shingling:** 0.59 seconds
- **MinHashing:** 3.38 seconds
- **LSH Banding:** 0.10 seconds
- **Verification:** 0.02 seconds

6.2. Speedup and Efficiency

The most critical metric for this research is the reduction in comparisons.

- **Total Possible Pairs:** 4,212,253 (**$O(N^2)$** complexity).
- **Candidate Pairs Found by LSH:** 2,807.
- **Reduction Factor:** The system eliminated 99.93% of necessary comparisons, achieving a **1500.6x speedup**.

6.3. Detection Accuracy

Upon verifying the 2,807 candidate pairs:

- **True Positives:** 17 pairs were confirmed to have a Jaccard similarity **≥ 80%**.
- **False Positives:** 983 pairs were candidates (shared a band) but had a final similarity **< 80%**.
- The false positives are an expected trade-off of LSH; they are computationally cheap to filter out in the final verification step compared to the millions of pairs successfully ignored.

6.4. Qualitative Analysis (Example)

The system successfully detected a high-confidence plagiarism instance between Document 1284 and Document 1455, which shared **91.7% similarity**.

Text Excerpt Detected:

"Is there anyone using sheep models for cardiac research, specifically concerned with arrhythmias, pacing or defibrillation? I would like to hear from you."

This detection confirms the system's ability to find near-duplicates, likely representing cross-posted messages in the newsgroups.

7. Future Work and Conclusion

Conclusion: This project successfully demonstrated that Locality-Sensitive Hashing is a viable and highly efficient solution for the document plagiarism problem. By reducing the complexity from quadratic to near-linear, we processed nearly 3,000 documents in seconds rather than hours. The experimental results, showing a 1500x reduction in comparisons, validate the theoretical efficiency of the MinHash + LSH pipeline.

Future Work: To further improve this system, future iterations could:

1. **Optimize k:** Experiment with larger shingle sizes (e.g., **k = 9**) to reduce false positives in the candidate set.
2. **Scale Up:** Test on the full 20,000 document dataset or Web Crawl data (Common Crawl).
3. **Parallelization:** The MinHashing step (Stage 2) took the longest (3.38s). This is "embarrassingly parallel" and could be significantly sped up using multi-threading or GPU acceleration.
